

Incident report analysis

Summary	The company had a DoS attack. The attacker sent many ICMP ping packets through a firewall that was not set up correctly. This caused the network to stop working for about 2 hours. Employees could not use the network or company services. The IT team blocked the ICMP traffic, stopped non-important services, and restored the important services. After the attack, the team updated the firewall, added IP address checks, network monitoring, and an IDS/IPS.
Identify	The security team checked the network, firewall, and system logs to find the cause of the attack. They found that the firewall was not configured correctly, which allowed the attacker to send many ICMP packets into the network. This caused a DoS attack that affected the internal network and company services.
Protect	The team updated the firewall settings and added a rule to limit ICMP traffic. They also enabled IP address verification to block fake IP addresses. The company will do regular firewall checks, security updates, and staff training to help prevent future attacks.
Detect	The team will use network monitoring tools and an IDS/IPS to watch for unusual network traffic. They will also check firewall logs and set alerts to quickly detect suspicious ICMP traffic or other attacks.
Respond	If this happens again, the team will block the malicious traffic, isolate affected systems if needed, and keep important services running. They will collect firewall logs and network data to investigate the attack. After the incident, they will review what happened and improve the response plan
Recover	The team will restore all network services and make sure the systems are working normally. They will restore any lost data from backups if needed and continue to monitor the network for new attacks. They will also update the recovery plan to improve future response.

Reflections/Notes: I learned that a small security problem can cause a big network attack. This incident showed me why it is important to configure firewalls correctly, monitor network traffic, and respond quickly to security incidents. Regular security checks and updates can help prevent similar attacks in the future.
